Abstract: Maternal transcripts are indispensable and play an essential role in regulation of the resumption of meiosis, nuclear reprogramming and subsequent development. In this study, we conducted interactive subtraction analysis to investigate the dynamic changes in the gene expression profiles of mouse oocytes after artificial activation. To accomplish this, we compared the cDNA libraries of freshly ovulated metaphase II (MII) oocytes and pronuclear-stage eggs at 8 h after activation, which were obtained by interactive subtraction. After constructing the cDNA libraries, we sequenced 635 subtracted clones of differentially expressed genes and the identities of 515 of these genes were determined by online BLAST analysis. The analysis revealed that genes down-regulated after activation were mainly responsible for enzyme and receptor activities, and also for DNA, chromatin, ATP, protein, and ion binding. On the other hand, genes upregulated after activation were mainly responsible for enzyme activities, ion binding, and the maintenance of cell structure. For further insight into the functions of the genes, gene network analysis was performed, and in order to validate differential gene expression, the gene expression levels were determined by using real-time quantitative PCR. The present analysis was capable of identifying the genes that changed dynamically following the resumption of meiosis, and these genes may control the developmental programs in oocytes and preimplantation embryos.

II (MII) stage, resume meiosis at fertilization. Meiotic resumption is triggered by repeated Ca²⁺ oscillations that are generated by sperm derived phospholipase C (PLC) ζ , following which the fertilized eggs start to develop [1]. The oocytes also deposit various maternal genome-derived transcriptional products in their bulky cytoplasm during the growth period. These maternal transcripts are indispensable and also play an essential role in the regulation of meiotic resumption, nuclear reprogramming and the subsequent development. Once an oocyte is activated and starts developing, the maternal transcripts are selectively degraded [2-4]. Meanwhile, the synthesis of new embryonic genomederived transcripts is initiated several hours after oocyte activation [5-8]. The temporal-spatio-specific dynamism involved in the synthesis of these transcriptional products, which is precisely regulated during development in the preimplantation stage, possibly plays an important role in postimplantation development.

To obtain an insight into the temporal-spatio-specific dynamism involved in the synthesis of the transcriptional products by oocytes and embryos, numerous comprehensive gene expression analyses have been conducted using mRNA differential display [5-8], cDNA microarray [8-10], and analysis of expressed sequence tags (EST) [7, 11]. From the large cohort of maternal transcripts identified by the global gene expression analysis, several important genes that are critical for the progress of the chain of events following meiotic resumption and early development have been identified for example, cellular Moloney murine sarcoma sequence (c-mos) [12-15] and tissue plasminogen activator (Plat) [16-19] that regulate meiotic resumption and the NLR family, the pyrin domain containing 5 (NIrp5) [20-23], and zygote arrest 1 (Zar1) [24] genes that are required for development beyond the 2-cell stage. Although, considerable

information has been accumulated regarding gene expression in very early stage embryos, many factors remain to be explained. We need to gather additional transcriptome information in order to understand the complete mechanism underlying the transition from maternal to embryonic regulation of development, which has long-term effects on full-term development. Furthermore, as the next step in studying the molecular mechanisms underlying the early development, it is important to select a smaller number of genes that are candidates for important roles in development.

Accordingly, in this study, we carried out subtraction analysis using mouse eggs at the following 2 stages: freshly ovulated MII oocytes and parthenogenetic eggs at 8 h after artificial activation. Here, we used artificially activated 1-cell embryos in order to eliminate transcripts derived from paternal genomes. In order to validate the dynamic changes in gene expression, we further assessed their gene expression levels quantitatively by using the real-time polymerase chain reaction (PCR). The present analysis was capable of identifying the gene expressions which were dynamically changed following meiotic resumption, and these genes may govern the developmental programs in oocytes and preimplantation embryos in mice.

Materials and Methods

Animals

For subtraction analysis, adult female B6C3F1 (C57BL/6NCrj × C3H/HeNJcl) mice were obtained from Clea Japan Inc. (Tokyo, Japan). For gene expression analysis, adult female CD-1 mice were obtained from Charles River Laboratories Japan, Inc. (Yokohama, Japan). During the course of the experiments, the mice were provided with food and water *ad libitum*, and maintained under controlled conditions of temperature $(23^{\circ}C \pm 2^{\circ}C)$, humidity (40%–60%) and a 12 h light and 12 h dark cycle. All the mice were maintained and used in accordance with the guidelines for the care and use of laboratory animals, as specified by the Japanese Association for Laboratory Animal Science and Tokyo University of Agriculture.

Oocyte and embryo collection

Ovulated MII oocytes were collected from mature B6C3F1 female mice after superovulation induced by consecutive injections of 5 IU equine chorionic gonadotrophin (eCG) and 5 IU human chorionic gonadotrophin (hCG) which were administered 48 h apart. Cumulus cells were removed by treatment with hyaluronidase (300 IU/ml) in M2 medium. For the production of diploid pronuclear stage eggs by artificial activation, the oocytes were cultured for 4 h in a drop of Ca²⁺-free M16 medium containing 10 mM SrCl₂ (Sigma-Aldrich, MO) that was added to induce repeated intracytoplasmic Ca2+ oscillations and oocyte activation, and 5 μ g/ml cytochalasin B (Sigma-Aldrich) that was added to induce diploidy by the inhibition of second polar body extrusion. After the first 4 h of culture in the M16 medium, only those activated eggs that formed 2 female pronuclei without polar body extrusion were selected and cultured further in potassium simplex-optimised medium (KSOM) [25] at 37°C for 4 h. The MII oocytes and activated eggs were then collected in a lysis buffer at 15-16 h and 24-25 h post-hCG injection, respectively. All in vitro cultures were performed under an atmosphere of 5% CO₂, 5% O₂, and 90% N_2 .

Total RNA preparation and cDNA subtraction analysis

Total RNA was isolated using an RNeasy[®] Mini Kit (Qiagen. K.K. Tokyo, Japan) from each of the approximately 3,000 MII oocytes and 1-cell embryos. The samples were immediately lysed in 350 μ l of buffer, RNeasy lysis thioyanate (RLT), and homogenised by vortexing. After adding 1 volume of 70% ethanol, each lysate was applied to a RNeasy Mini spin column. The total RNA bound to the membrane was eluted in RNasefree water. Using this RNA, cDNA was synthesized and then amplified using the switch mechanism at the 5' end of RNA transcripts with (SMART™) PCR cDNA Synthesis Kit (Clontech/ Takara bio Inc., Shiga, Japan), according to the manufacturer's instructions. cDNA subtraction was performed using a PCR-select™ cDNA Subtraction Kit (Clontech) according to the manufacturer's instructions. The subtracted PCR products were subcloned into pGEM[®]-T Easy vector (Promega Co., WI) for screening. Next, the subtracted clones were differentially screened using PCR-Select Differential Screening Kit (Clontech). The inserted sequences of the subtracted clones were amplified by PCR using forward (TCGAGCGGCCGGCCGGGCAGGT) and reverse (AGCGTGGTCGCGGCCGAGGT) polylinker primers, and the PCR products were immobilized on nylon membranes in triplicate.

Hybridization probes were prepared by labeling the forward- and reverse-subtracted cDNA (20–90 μ g) and forward- and reverse-unsubtracted cDNA (50–100 μ g) libraries with digoxigenin (DIG; Roche Molecular Biochemicals, Basel, Switzerland). Subsequently, the PCR products immobilized on the nylon membranes were hybridized with 100 ng of each probe at 72°C for 60

min; the probes were prepared in ExpressHyb Hybridization Solution (Clontech). After rinsing, the hybridization signals of the membrane were read using a FujiFilm LAS-1000 Plus camera (Fujifilm Co., Tokyo, Japan), and the signal intensity was computed using FujiFilm ArrayGauge software (Fujifilm). The cDNA clones that hybridized with the forward-subtracted and forward-unsubtracted probes but not to the reversesubtracted and reverse-unsubtracted probes were determined as specific to the MII oocytes and activated eggs. The results of the differential screening revealed that certain cDNA clones demonstrated a 2-fold increase in gene expression in the MII oocytes compared with the activated eggs. These genes were classified as MII oocyte-specific genes. The cDNA clones from the MII oocytes that exhibited respective signal intensities 2-fold weaker than those of the activated eggs were classified as activated egg-specific genes.

DNA sequencing analysis and BLAST search

DNA sequencing was performed using an automated ABI PRISM3130 Genetic Analyzer (ABI, CA). Sequencing reactions were carried out with the BigDye Terminator v3.1 Cycle Sequencing Kit (ABI) using forward and reverse primers. The sequences obtained were compared against those in the Mouse Genome Informatics (MGI; http://www.informatics.jax.org/) database by using the online basic local alignment search tool (BLAST) analysis (www.ncbi.nlm.niho.gov/ BLAST).

Quantitative gene expression analysis

cDNA was synthesized from ovulated MII oocytes and artificially activated eggs by using a Cells-to-cDNA™ II kit (Ambion, Inc., TX). Single blastocysts were placed in 13 μ l of the lysis buffer and then treated with DNase. The cDNAs were synthesized in 20 μ l of reaction solution by using a SuperScript RNase H-reverse transcriptase kit (Invitrogen, Co., CA). Further, this synthesized cDNA was employed for the quantitative analysis of gene expression using RT-PCR, which was carried out using a ready-to-use reaction mixture kit (LightCycler[™] FirstStart DNA Master SYBR Green I; Roche Molecular Biochemicals). The primer sequences used for the PCR reaction, PCR conditions, and product sizes are listed in Table 1. The glyceraldehydes-3phosphate dehydrogenase (*Gapdh*) gene was used as the loading control. The amplification protocol was as follows: DNA polymerase activation at 95°C for 10 min and 45 cycles of amplification with denaturation at 95°C for 15 s, annealing for 10 s at the optimum temperature

for each gene (see Table 1), and extension at 72°C for 10 s. On completion of these amplification cycles, a melting curve analysis was performed to verify specific amplification. The relative expression levels of each gene tested were obtained from the standard curve that was generated using a pooled cDNA mixture extracted from E12.5 foetuses.

Statistical analysis

The gene expression levels were statistically analyzed using Student's *t*-test. Differences were considered significant at p<0.05 and greatly significant at p<0.01. In order to elucidate the functional network of the genes that were differentially expressed in the MII oocytes and those that were differentially expressed in the activated eggs at 8 h after oocyte activation. The gene lists were integrated into the Ingenuity Pathway Analysis (IPA) database (Ingenuity, CA).

Results and Discussion

Identification of differentially expressed genes

To identify genes that were differentially expressed following oocyte activation, we compared the cDNA libraries of freshly ovulated MII oocytes and activated eggs, obtained by interactive subtraction technology (Table 2). Total RNA was isolated from each of the approximately 3,000 MII oocytes and the pronuclear stage eggs at 8 h after activation, and the cDNA libraries were established for interactive subtraction analysis. cDNA subtraction was performed using the PCR-Select Subtraction Kit (Clontech), which combines the normalization and equalization of cDNA with the subtraction process. From the subtracted cDNA libraries, 2,304 cDNA clones were subcloned, and the forward and reverse sequences were subjected to probe hybridization in order to identify the differentially expressed genes (Table 2). We sequenced 635 subtracted clones that demonstrated approximately 2-fold or greater difference in the intensity of the hybridization signals between the subtracted forward and the reverse probes, and the identities of 515 of these genes were determined by online BLAST analysis. This set comprised 217 known genes (121 and 96 genes were strongly expressed in MII oocytes and activated eggs, respectively) and 181 novel or uncharacterized genes (29 and 152 genes strongly expressed in MII oocytes and activated eggs, respectively). The number of known genes represents the total number of genes remaining after the overlapping ones were excluded. The differentially expressed known genes, which were obtained by hybridization analysis

with forward subtracted and unsubtracted probes and with reverse subtracted and unsubtracted probes, were classified into 3 groups: Group A genes were detected by both subtracted and unsubtracted probes; Group B genes were detected by only subtracted probes; Group C genes were detected by only unsubtracted probes.

To understand the functions of the genes with dynamically changed expressions after oocyte

activation, we performed a cluster analysis for Group A genes (21 and 27 genes from the MII oocytes [Table 3] and activated eggs [Table 4], respectively) by using the MGI database (http://www.informatics.jax.org/). The results revealed that the genes down-regulated after activation were mainly responsible for enzyme and receptor activities and also for DNA, chromatin, ATP, protein, and ion binding (Table 3). On the other hand,

Table 4. Genes up-regulated after oocyte activation

parthenogenetically activated eggs, all cDNA clones represented maternal genome-derived transcripts. The cDNA library for MII oocytes comprised well-known genes that are expressed at high levels in MII oocytes: linker histone (*H1oo*) [4, 26–29], growth differentiation factor 9 (*Gdf9*) [4, 29], and *Plat* [4, 9]. Similarly, the cDNA library for activated eggs comprised genes that

are known to be activated after fertilization: sprouty 4 (*Spry4*) [9, 29, 30] and karyopherin-alpha2 (*Kpna2*) [10]. We believe that the present interactive subtraction analysis successfully detected a substantial number of genes that are differentially expressed at the abovementioned stages.

Fig. 1. Quantitative analysis of the gene expression in Mll oocytes and activated eggs. The genes were selected from the list of genes differentially expressed in Mll oocytes and activated eggs, as determined by cDNA subtraction analysis. The relative mRNA expression levels were calculated by determining the intensity of gene expression using *Gapdh* as internal control. The ordinate shows the mean of the relatively expressed levels. The values denote the mean \pm S.E. obtained from 3 independent experiments. Asterisks denote significant difference between the oocytes and activated eggs (*p<0.05, **p<0.01).

Validation of subtraction data by Q-PCR

We validated our results of gene expression levels by using real-time quantitative PCR. From Group A, we examined 14 and 3 genes that were identified as having been specifically expressed in the MII oocytes and activated eggs, respectively (Fig. 1). The quantitative PCR analysis revealed that out of the 14 genes tested, 3 MII oocytes-specific genes, including Plat, glycerophohodiester phosphodiesterase domain containing 1 (Gdpd1) and integrator complex subunit 9 (Ints9), were expressed at levels 5-fold higher than in the activated eggs. The differences in the expression levels were greatly significant at p < 0.01levels. Moreover, 6 genes, lamin B-receptor (Lbr), interleukin 1 receptor accessory protein (*ll1rap*), xenotropic and polytropic retrovirus receptor 1 (Xpr1), Gdf9, solute carrier family 7 member 1 (Slc7a1) and solute carrier family 23 member 2 (S/c23a2), were expressed at significantly (p<0.05) higher levels in the activated eggs. In contrast, 3 genes whose expressions were elevated after oocyte activation, including sprouty homolog 4 (Spry4), karyopherin (importin) alpha 2 (Kpna2) and exocyst complex component 1 (Exoc1) were expressed at levels of 2-fold or more in the activated eggs, however, significant differences were not seen. Gapdh gene, which was tested as the internal control, demonstrated almost equal expression levels in both the MII oocytes and activated eggs.

The present data is representative of genes expressed specifically in the MII oocytes and activated eggs, because the results of real-time PCR correlated well with those of the subtraction analysis. Accordingly, we believe that the present interactive subtraction analysis successfully detected a substantial number of differentially expressed genes, and identified a small number of candidate genes that may significantly contribute to future studies into the molecular mechanisms in oocytes.

Networks

In order to obtain further insight into the function of the genes classified into Group A, gene networks were constructed using the IPA database. The first 5 functional networks in each case are shown in Fig. 2a, b and Tables 5 and 6.

Gene networks constructed using genes expressed specifically in the MII oocytes were as follows (Fig. 2a, Table 5). Network 1 (*Plat*): cellular movement, cardiovascular system development and function, and organismal development. Network 2 (*Gdf9*): DNA replication, DNA recombination, and DNA repair, cell cycle regulation, and cellular assembly and organization. Network 3 (solute carriers family 23 member 1 [*Slc23a*]): lipid metabolism, small molecule biochemistry, and cell death. Network 4 (*Slc7a1*, dyskeratosis congenital 1 [*Dkc1*]): DNA replication, DNA recombination, DNA repair; cell cycle regulation, and connective tissue development and function. Network 5 (*Plat*): cellular assembly and organization, anticancer effect, and cell cycle regulation.

The networks constructed using genes with rapidly enhanced expressions after oocyte activation were as follows (Fig. 2b, Table 6). Network 1 (Kpna2): cellular movement, cardiovascular system development and function, and organismal development. Network 2 (Exoc1): DNA replication, DNA recombination, DNA repair, cell cycle regulation, and cellular assembly and organization. Network 3 (additional sexcombs-like 1 protein [Asx/1], non-POU-domain-containing, octomer binding protein [Nono]): lipid metabolism, small molecule biochemistry, and cell death. Network 4 (aldoketo reductase family 1, member B1 [Akrb1]): DNA replication, DNA recombination, DNA repair, cell cycle regulation, and connective tissue development and function. Network 5 (epidermal growth factor receptor pathway substrate 15-like 1 [Eps15/1], stanniocalcin 2 [Sct2]): cellular assembly and organization, anticancer effect, and cell cycle regulation.

Genes expressed specifically in the MII oocytes were primarily involved in the cell cycle and cancer. Furthermore, the networks generated from these genes also suggest that the genes highly expressed in MII oocytes are involved in the cell cycle and are responsible for cell proliferation. In addition to the cell cycle and cancer, the genes with significantly enhanced expressions after activation were involved in cell proliferation and cell adhesion. This result is fairly understandable because it is expected that the genes responsible for the cell cycle and development would be activated following the resumption of meiosis and subsequent development.

Although cDNA microarray analysis is a robust technique for the identification of genes that are specifically expressed in particular cells and tissues, it is complementary to subtractive hybridization analysis [31]. Recently, a microarray study presented several novel findings regarding gene expression profiles in early-stage embryos [32]. For example, fertilization leads to extensive changes in the transcript profiles, which are much greater than previously recognized, and genome activation during the 2-cell stage may be selective on a qualitative scale with genes involved in transcription and RNA processing. Cui et al. (2007) [8] reported a comparison of gene expression profiles of germinal vesicle (GV)- and MII-stage oocytes. Their results indicate that the genes specifically up-regulated in MII oocytes are more likely to be involved in DNA replication, amino acid metabolism, and the expression

Mll oocytes. The network is displayed graphically as nodes (genes or gene products) and edges (the biological relationships between nodes, including functional or physical interactions, e.g., E, expression; B, binding). The shape of the objects (e.g., circle, diamond) represents whether the protein is a structural protein, transcription factor, etc. The family classes represented by these shapes are listed in Tables 3 and 4. The continuous and dashed lines indicate direct and indirect interactions, respectively, between the gene products.

Network ID	Genes in network	Categories of top functions	
1	Akt, ATF2, CCNB1, CDH1, Ck2, DCLRE1A, EIF2B1, FGF3, FRAP1, GNA13, GNB2L1, Hsp70, HSP90AA1, HSP90AB1, IL1RAP, Jnk, LAMA3, MAP4K5, Mapk, MDK, MIA, MOS, NCL, NOLC1, MAPK14, Pdgf Ab, PDGF BB, PLAT, Ras, RFPL4A, SERPINF1, SIN3A, SNCG, TP53BP1	Cellular Movement, Cardiovascular System Development and Function, Organismal Development	
2	AKT1, AKT3, amino acids, APPL1, ATP7A, BMP15, CBX5, CYP17A1, DCP1A, DLG4, DLG4P2, GAPVD1, GDF9, GGTA1, HSPA4L, IGFBP5, INHA, KIF1C, LBR, LMO7, LRP2, MAG12, MATR3, MOS, MYOD1, NP, NPC1, palmitic acid, PLA2G4C, progesterone, PTGER2, PTPN21, SRPK1, STAR, YWHAG	Cancer, Lipid Metabolism, Molecular Transport	
3	APC, BPGM, CD44, CDC2, CDKN2A, CENPE, CENPF , CNOT7 , CNOT6L, DDX3X , EDN1, Erm, FBXL5 , GNA13, IARS (includes EG:3376), IL4, IL13, JAG1 , LOX, MDM4 , MFAP2, MME, MSN, MYC, PDGF-CC, PDIA6 , RDX , SLC23A2 , SLC43A3, SMOC2, SPN, SUMO2 , TGFB1, THY1, TOB2	Cancer, Cellular Growth and Proliferation, Tumor Morphology	
4	AIFM1, AKT3, beta-estradiol, BUB3, BUB1B, CDC20, CDKN1A, CENPE, CLU, DDIT4, DKC1, hydrogen peroxide, IGFBP2, KCNN2, LRRC17, MAD2L1, MCC, MLLT10, NCAPD3, PAX3, PLK4, PRC1, PTPN2, RAP1A, SLC3A2, SLC7A11, SLC9A1, SMARCB1, SMC4, SNCG, SPAG5, SS18, TERC (includes EG:7012), TERT, TXNIP	Cancer, Cellular Growth and Proliferation, Cell Death	
5	ACADS, APC, CRH, CTGF, EIF4EBP2, FADD, FGF3, HNRPF, IGFBP2, IGFBP3, INHBA, INS1, LNPEP, LOX, MAPK3, MBD4, MEIS2, MIF, NFRKB, NIF3L1, NUP98, NUP107, NUP133, NUP160, PHIP, PLAT, RAPGEF4, retinoic acid, SERPINB2, SERPINE2, SMAD2, SYTL4, TNF, TNFAIP6, TPD52L2	Cancer, Cellular Growth and Proliferation, Cell Cycle	

 Table 5. Top 5 networks generated from the IPA for genes specifically expressed in MII oocytes

The genes with bold letters were in the cDNA library obtained by the subtraction analysis.

Network ID	Genes in network	Categories of top functions
1	AURKB, CENPF, CREBBP , CYP2J2, ELK3, ELP2, ELP3, ELP4, ELP5, ELP6, ETV5, Histone h3, HSPA8 , IKBKAP, KPNA2 , Mapk, MERTK , MYST2 , NUP214 , NXF1 , PDGF BB, PI3K, PIK3CB, PIK3CD, PIK3CG, PIK3R5 , PLC gamma, PTHLH, QARS , SH2B2, SH3BP2, SMOC2, SPRY4 , VAV3	Immune Response, Cell Signaling, Cell-To-Cell Signaling and Interaction
2	ADK, BCAT1, COPS4, DST, DYNC111, EIF4ENIF1, EXOC1, EXOC2, EXOC3, EXOC4, EXOC5, EXOC7, EXOC8, F2, GTP, HNRPK, ICOSLG, IFNG, IL15, MYC, ND1, ND2, ND4, ND5, ND6, ND4L, PARD6G, PLEK, PPP1R12A, PRDX2, PRPF8, SMAD3, SP110, VBP1, YWHAZ	Vitamin and Mineral Metabolism, Cell-To-Cell Signaling and Interaction, Hematological System Development and Function
3	ABL2, ACO1, ACO2, ADSS, ASXL1, BID, CD27, CENPF, CSF2, CYP19A1, dihydrotestosterone, EFNA1, ELAVL1, EPHA2, FGF7, FTL1, GMPS, hydrogen peroxide, MYST1, NACA, NONO, PDCD4, PTP4A3, RB1, retinoic acid, RPA1, SFPQ, SGK, SIVA1, SMARCA2, TMEM97, TOP1, TP53, TP53BP1, TUBA4A	Cell Cycle, Cancer, Cellular Growth and Proliferation
4	AKR1B1, BCAR1, BCL2, BCLAF1, BGLAP, BID, BRCA1, BRCC3, CCNB1, CDC2, cholecalciferol, CNIH, COL2A1, E2f, Fgf, FGF2, FOSL2, GATA4, GL12, IL11, JARID2, KBTBD8, NFYC, NKX2-5, NPY, NUSAP1, ODC1, PAX8, POU3F4, PTHLH, SHH, SOX9, TGFB1, WDR76, ZFP57	Embryonic Development, Tissue Development, Cancer
5	AKAP5, beta-estradiol, BGLAP, BRAF, CNTN1, CRK, DLG1, DLG3, DLG4, DLGAP2, EFNA1, ELOVL3 , EPN2 , EPS15, EPS15L1 , ERC2, FOSL2, GRASP, MAG12, NARF , norepinephrine, NPFFR2, NPY, OPRM1, PTP4A1, RAB6A, RIMS1, SMARCA4, SNAP25, SPRY2, STC2 , STON2, STX1A, STXBP6 (includes EG:29091), UNC13A	Cancer, Endocrine System Disorders, Molecular Transport

The genes with bold letters were included in the cDNA library obtained by the subtraction analysis.

of G protein-coupled receptors and signalling molecules. It has also been reported that the transcripts encoding components of signalling pathways essential for maintaining the unique characteristics of the MIIarrested oocyte, such as those involved in protein kinase pathways, are the most prominent among the stable transcripts [33].

The present results also provide a comprehensive profile of the dynamism in gene expression following oocyte activation in mice. Further understanding of the biological role of these genes would increase our knowledge regarding the meiotic cell cycle, maternal genome activation, chromatin remodeling, pluripotency, early cleavage, and epigenetic reprogramming. We believe that the approach we have described in which differential gene expression can be identified will lead to a better understanding of the molecular mechanisms underlying the unique functions of these genes in oocytes, including their long-term effects on oocyte development.
